

Testing

Advanced functional programming - Lecture 2

Wouter Swierstra and Alejandro Serrano

Program Correctness

Universiteit Utrecht

[Faculty of **Science**
Information and Computing **Sciences**]

Testing and correctness

- ▶ When is a program correct?

Testing and correctness

- ▶ When is a program correct?
- ▶ What is a specification?
- ▶ How to establish a relation between the specification and the implementation?
- ▶ What about bugs in the specification?

Equational reasoning

- ▶ “Equals can be substituted for equals”
- ▶ In other words: if an expression has a value in a context, we can replace it with any other expression that has the same value in the context without affecting the meaning of the program.
- ▶ When we deal with infinite structures: two things are equivalent if we cannot find out about their difference:

Equational reasoning

- ▶ “Equals can be substituted for equals”
- ▶ In other words: if an expression has a value in a context, we can replace it with any other expression that has the same value in the context without affecting the meaning of the program.
- ▶ When we deal with infinite structures: two things are equivalent if we cannot find out about their difference:

ones = 1: ones
ones ' = 1:1: ones '

Referential transparency

In most functional languages like ML or OCaml, there is no referential transparency:

```
let  val  x      =  ref 0
      fun  f n    =  (x := !x + n; !x)
in    f 1 + f 2
```

Referential transparency

In most functional languages like ML or OCaml, there is no referential transparency:

```
let val x      = ref 0
    fun f n    = (x := !x + n; !x)
in   f 1 + f 2
```

But we cannot replace the last line with $1 + f\ 2$, even though $f\ 1 = 1$.

Referential transparency in Haskell

- ▶ Haskell is referentially transparent – all side-effects are tracked by the IO monad.

do

```
x <- newIORef 0
let f n = do modifyIORef x (+n); readIORef x
r <- f 1
s <- f 2
return (r + s)
```

Note that the type of `f` is `Int -> IO Int` – we cannot safely make the substitution we proposed previously.

Referential transparency

Because we can safely replace equals for equals, we can *reason* about our programs – this is something you already saw in the course on functional programming.

For example to prove some statement $P\ xs$ holds for all lists xs , we need to show:

- ▶ $P\ []$ – the base case;
- ▶ for all x and xs , $P\ xs$ implies $P\ (x:xs)$.

Equational reasoning

- ▶ Equational reasoning can be an elegant way to prove properties of a program.
- ▶ Equational reasoning can be used to establish a relation between an “obviously correct” Haskell program (a specification) and an efficient Haskell program.
- ▶ Equational reasoning can become quite long...
- ▶ Careful with special cases (laziness):
 - ▶ undefined values;
 - ▶ partial functions;
 - ▶ infinite values.

You can formalize such proofs in other systems such as Agda, Coq or Isabelle.

QuickCheck

QuickCheck, an automated testing library/tool for Haskell

Features:

- ▶ Describe properties as Haskell programs using an embedded domain-specific language (EDSL).
- ▶ Automatic datatype-driven random test case generation.
- ▶ Extensible, e.g. test case generators can be adapted.

History

- ▶ Developed in 2000 by Koen Claessen and John Hughes.
- ▶ Copied to other programming languages: Common Lisp, Scheme, Erlang, Python, Ruby, SML, Clean, Java, Scala, F#
- ▶ Erlang version is sold by a company, QuviQ, founded by the authors of QuickCheck.

Case study: insertion sort

```
isort :: Ord a => [a] -> [a]
isort []      = []
isort (x:xs)  = insert x (isort xs)
```

```
insert :: Ord a => a -> [a] -> [a]
insert x []      = [x]
insert x (y:ys)
  | x <= y      = x : y : ys
  | otherwise   = y : insert x ys
```

Properties of insertion sort

We can now try to prove that for all lists `xs`,
`length (sort xs) == length xs`.

- ▶ The base case is trivial.
- ▶ The inductive case requires a lemma relating `insert` and `length` – suggestions?

Case study: insertion sort

Consider the following (buggy) implementation of insertion sort:

```
sort :: [Int] -> [Int]
sort []      = []
sort (x:xs)  = insert x xs
```

```
insert :: Int -> [Int] -> [Int]
insert x []                                = [x]
insert x (y:ys) | x <= y                    = x : ys
                | otherwise                 = y : insert x ys
```

Let's try to debug it using QuickCheck.

How to write a specification?

A good specification is

- ▶ as precise as necessary,
- ▶ no more precise than necessary.

A good specification for a particular problem, such as sorting, should distinguish sorting from all other operations on lists, without forcing us to use a particular sorting algorithm.

A first approximation

Certainly, sorting a list should not change its length.

```
sortPreservesLength :: [Int] -> Bool
sortPreservesLength xs =
    length (sort xs) == length xs
```

We can test by invoking the function :

```
> quickCheck sortPreservesLength
Failed! Falsifiable, after 4 tests:
[0,3]
```

Correcting the bug

```
sort :: [Int] -> [Int]
sort []      = []
sort (x:xs)  = insert x xs
```

```
insert :: Int -> [Int] -> [Int]
insert x []                        = [x]
insert x (y:ys) | x <= y          = x : ys
                | otherwise       = y : insert x ys
```

Which branch does not preserve the list length?

A new attempt

```
> quickCheck sortPreservesLength  
OK, passed 100 tests.
```

Looks better. But have we tested enough?

Properties are first-class objects

$(f \text{ `preserves` } p) \ x = p \ x == p \ (f \ x)$

`sortPreservesLength = sort `preserves` length`

`idPreservesLength = id `preserves` length`

Properties are first-class objects

$(f \text{ `preserves` } p) \ x = p \ x == p \ (f \ x)$

`sortPreservesLength = sort `preserves` length`

`idPreservesLength = id `preserves` length`

So `id` also preserves the lists length:

```
> quickCheck idPreservesLength  
OK, passed 100 tests.
```

We need to refine our spec.

When is a list sorted?

We can define a predicate that checks if a list is sorted:

```
isSorted :: [Int] -> Bool
isSorted []      = True
isSorted [x]     = True
isSorted (x:y:xs) = x < y && isSorted (y:xs)
```

And use this to check that sorting a list produces a list that isSorted.

Testing again

```
> quickCheck sortEnsuresSorted  
Falsifiable, after 5 tests:  
[5,0,-2]  
> sort [5,0,-2]  
[0,-2,5]
```

We're still not quite there...

Debugging sort

What's wrong now?

```
sort :: [Int] -> [Int]
sort []      = []
sort (x:xs)  = insert x xs
```

```
insert :: Int -> [Int] -> [Int]
```

Debugging sort

What's wrong now?

```
sort :: [Int] -> [Int]
sort []      = []
sort (x:xs)  = insert x xs
```

```
insert :: Int -> [Int] -> [Int]
```

We are not recursively sorting the tail in sort.

Another bug

```
> quickCheck sortEnsuresSorted  
Falsifiable, after 7 tests:  
[4,2,2]
```

```
> sort [4,2,2]  
[2,2,4]
```

This is correct. What is wrong?

Another bug

```
> quickCheck sortEnsuresSorted  
Falsifiable, after 7 tests:  
[4,2,2]
```

```
> sort [4,2,2]  
[2,2,4]
```

This is correct. What is wrong?

```
> isSorted [2,2,4]  
False
```

Fixing the spec

The isSorted spec reads:

```
sorted :: [Int] -> Bool
sorted []      = True
sorted (x:[])  = True
sorted (x:y:ys) = x < y && sorted (y : ys)
```

Why does it return False? How can we fix it?

Are we done yet?

Is sorting specified completely by saying that

- ▶ sorting preserves the length of the input list,
- ▶ the resulting list is sorted?

Are we done yet?

Is sorting specified completely by saying that

- ▶ sorting preserves the length of the input list,
- ▶ the resulting list is sorted?

No, not quite.

```
evilNoSort :: [Int] -> [Int]  
evilNoSort xs = replicate (length xs) 1
```

This function fulfills both specifications, but still does not sort.

We need to make the relation between the input and output lists precise: both should contain the same elements – or one should be a permutation of the other.

Specifying sorting

```
permutes :: ([Int] -> [Int]) -> [Int] -> Bool  
permutes f xs = f xs `elem` permutations xs
```

```
sortPermutes :: [Int] -> Bool  
sortPermutes xs = sort `permutes` xs
```

This completely specifies sorting and our algorithm passes the corresponding tests.

How to use QuickCheck

To use QuickCheck in your program:

```
import Test.QuickCheck
```

Define properties.

Then call to test the properties.

```
quickCheck :: Testable prop => prop -> IO ()
```

The type of quickCheck

The type of is an *overloaded* type:

```
quickCheck :: Testable prop => prop -> IO ()
```

- ▶ The argument of is a property of type `prop`
- ▶ The only restriction on the type is that it is in the `Testable` *type class*.
- ▶ When executed, prints the results of the test to the screen – hence the result type.

Which properties are Testable?

So far, all our properties have been of type :

```
sortPreservesLength :: [Int] -> Bool  
sortEnsuresSorted  :: [Int] -> Bool  
sortPermutes       :: [Int] -> Bool
```

When used on such properties, QuickCheck generates random integer lists and verifies that the result is True.

If the result is for 100 cases, this success is reported in a message.

If the result is False for a test case, the input triggering the result is printed.

Other example properties

```
appendLength :: [Int] -> [Int] -> Bool
appendLength xs ys =
    length xs + length ys == length (xs ++ ys)
```

```
plusIsCommutative :: Int -> Int -> Bool
plusIsCommutative m n = m + n == n + m
```

```
takeDrop :: Int -> [Int] -> Bool
takeDrop n xs = take n xs ++ drop n xs == xs
```

```
dropTwice :: Int -> Int -> [Int] -> Bool
dropTwice m n xs =
    drop m (drop n xs) == drop (m + n) xs
```

Other forms of properties – contd.

```
> quickCheck takeDrop  
OK, passed 100 tests.
```

```
> quickCheck dropTwice  
Falsifiable after 7 tests.
```

```
1
```

```
-1
```

```
[0]
```

```
> drop (-1) [0]  
[0]
```

```
> drop 1 (drop (-1) [0])  
[]
```

Nullary properties

A property without arguments is also possible:

```
lengthEmpty :: Bool  
lengthEmpty = length [] == 0
```

```
wrong :: Bool  
wrong = False
```

```
> quickCheck lengthEmpty  
OK, passed 100 tests.
```

```
> quickCheck wrong  
Falsifiable, after 0 tests.
```

QuickCheck vs unit tests

No random test cases are involved for nullary properties.
QuickCheck subsumes unit tests.

Properties

Recall the type of `quickCheck`:

```
quickCheck :: Testable prop => prop -> IO ()
```

We can now say more about when types are `Testable`:

- ▶ testable properties usually are functions (with any number of arguments) resulting in a `Bool`

What argument types are admissible?

`QuickCheck` has to know how to produce random test cases of such types.

Properties – continued

```
class Testable prop where
  property :: prop -> Property

instance Testable Bool where
  ...

instance (Arbitrary a, Show a, Testable b) =>
  Testable (a -> b) where
```

We can test any Boolean value or any testable function for which we can generate arbitrary input.

More information about test data

```
collect :: (Testable prop, Show a) =>  
  a -> prop -> Property
```

The function gathers statistics about test cases. This information is displayed when a test passes:

```
> let sPL = sortPreservesLength  
> quickCheck (\xs -> collect (null xs) (sPL xs))  
OK, passed 100 tests.  
96% False  
4% True.
```

The result implies that not all test cases are distinct.

More information about test data – contd.

```
> quickCheck (\xs -> collect (length xs `div` 10)
                        (sPL xs))
```

```
+++ OK, passed 100 tests.
```

```
26% 0.
```

```
21% 1.
```

```
15% 2.
```

```
10% 5.
```

```
10% 3.
```

```
...
```

Most lists are small in size: QuickCheck generates small test cases first, and increases the test case size for later tests.

More information about test data (contd.)

In the extreme case, we can show the actual data that is tested:

```
> quickCheck (\ xs -> collect xs (sPL xs))
```

```
OK, passed 100 tests:
```

```
6% []
```

```
1% [9,4,-6,7]
```

```
1% [9,-1,0,-22,25,32,32,0,9,...
```

```
...
```

Why is it important to have access to the test data?

Implications

The function `insert` preserves an ordered list:

```
implies :: Bool -> Bool -> Bool
implies x y = not x || y
```

```
insertPreservesOrdered :: Int -> [Int] -> Bool
insertPreservesOrdered x xs =
    sorted xs `implies` sorted (insert x xs)
```

Implications – contd.

```
> quickCheck insertPreservesOrdered  
OK, passed 100 tests.
```

But:

```
> let iPO = insertPreservesOrdered  
> quickCheck (\x xs -> collect (sorted xs)  
                                (iPO x xs))
```

OK, passed 100 tests.

88% False

12% True

For **88** test cases, insert has not actually been relevant.

Implications – contd.

The solution is to use the QuickCheck implication operator:

```
(==>) :: (Testable prop) =>  
        Bool -> prop -> Property
```

```
instance Testable Property
```

The type allows to encode not only or , but also to reject the test case.

```
iP0 :: Int -> [Int] -> Property  
iP0 x xs = sorted xs ==> sorted (insert x xs)
```

Now, lists that are not sorted are discarded and do not contribute towards the goal of 100 test cases.

Implications – contd.

We can now easily run into a new problem:

```
iPO :: Int -> [Int] -> Property
iPO x xs = length xs > 2 && sorted xs ==>
           sorted (insert x xs)
```

We try to ensure that lists are not too short, but:

```
> quickCheck (\x xs -> collect (sorted xs)
                               (iPO x xs))
```

Arguments exhausted after 20 tests (100% True).

The chance that a random list is sorted is extremely small. QuickCheck will give up after a while if too few test cases pass the precondition.

Configuring QuickCheck

```
quickCheckWith :: Testable prop =>
  Args -> prop -> IO ()

data Args where
  replay :: Maybe (StdGen, Int)
    -- should we replay a previous test?
  maxSuccess :: Int
    -- max number of successful tests
    -- before succeeding
  maxDiscardRatio :: Int
    -- max number of discarded tests
    -- per successful test
  maxSize :: Int
    --max test case size
  ...
```

Generators

- ▶ Instead of increasing the number of test cases to generate, it is usually better to write a custom random generator.
- ▶ Generators belong to an abstract data type `Gen`. Think of as a restricted version of `IO`. The only effect available to us is access to random numbers.
- ▶ We can define our own generators using another domain-specific language. The default generators for datatypes are specified by defining instances of class `Arbitrary`:

```
class Arbitrary a where  
  arbitrary :: Gen a  
  ...
```

Generator combinators

```
choose      :: Random a => (a,a) -> Gen a
oneof       :: [Gen a] -> Gen a
frequency   :: [(Int, Gen a)] -> Gen a
elements    :: [a] -> Gen a
sized       :: (Int -> Gen a) -> Gen a
```

Simple generators

```
instance Arbitrary Bool where
  arbitrary = choose (False, True)

instance (Arbitrary a, Arbitrary b) =>
  Arbitrary (a,b) where
  arbitrary = do
    x <- arbitrary
    y <- arbitrary
    return (x,y)

data Dir = North | East | South | West
instance Arbitrary Dir where
  arbitrary = elements [North, East, South, West]
```

Generating random numbers

- ▶ A simple possibility:

```
instance Arbitrary Int where  
  arbitrary = choose (-20,20)
```

- ▶ Better:

```
instance Arbitrary Int where  
  arbitrary = sized (\ n -> choose (-n,n))
```

- ▶ QuickCheck automatically increases the size gradually, up to the configured maximum value.

How to generate sorted lists

Idea: Adapt the default generator for lists.

The following function turns a list of integers into a sorted list of integers:

```
mkSorted :: [Int] -> [Int]
```

```
mkSorted [] = []
```

```
mkSorted [x] = [x]
```

```
mkSorted (x:y:ys) = x : mkSorted ((x + abs y : ys))
```

For example:

```
> mkSorted [1,2,-3,4]  
[1,3,6,10]
```

Random generator

The generator can be adapted as follows:

```
genSorted :: Gen [Int]
genSorted = do
    xs <- arbitrary
    return (mkSorted xs)
```

Using a custom generator

There is another function to construct properties provided by QuickCheck, passing an explicit generator:

```
forall :: (Show a, Testable b) =>  
  Gen a -> (a -> b) -> Property
```

This is how we use it:

```
iP0 :: Int -> Property  
iP0 x = forall genSorted  
  (\ xs -> length xs > 2 && sorted xs ==>  
    sorted (insert x xs))
```

Loose ends: Shrinking

Arbitrary revisited

```
class Arbitrary a where  
  arbitrary :: Gen a  
  shrink :: a -> [a]
```

The other method in is

```
shrink :: (Arbitrary a) => a -> [a]
```

- ▶ Maps each value to a number of ‘structurally smaller’ values.
- ▶ When a failing test case is discovered, is applied repeatedly until no smaller failing test case can be obtained.

Program coverage

To assess the quality of your test suite, it can be very useful to use GHC's *program coverage* tool:

```
$ ghc -fhpc Suite.hs --make
$ ./Suite
$ hpc report Suite --exclude=Main --exclude=QC
  18% expressions used (30/158)
    0% boolean coverage (0/3)
      0% guards (0/3), 3 unevaluated
      100% 'if' conditions (0/0)
      100% qualifiers (0/0)
  ...
```

This also generates a .html file showing which code has (not) been executed.

<u>module</u>	<u>Top Level Definitions</u>			<u>Alternatives</u>			<u>Expressions</u>		
	%	covered / total		%	covered / total		%	covered / total	
module Prettify2	42%	9/21	<div><div></div></div>	23%	8/34	<div><div></div></div>	18%	30/158	<div><div></div></div>
Program Coverage Total	42%	9/21	<div><div></div></div>	23%	8/34	<div><div></div></div>	18%	30/158	<div><div></div></div>

screenshot

```

25 data Doc = Empty
26           | Char Char
27           | Text String
28           | Line
29           | Concat Doc Doc
30           | Union Doc Doc
31           deriving (Show,Eq)
32
33 {- /snippet Doc -}
34
35 instance Monoid Doc where
36     mempty = empty
37     mappend = (<>)
38
39 {- snippet append -}
40 empty :: Doc
41 (<>) :: Doc -> Doc -> Doc
42 {- /snippet append -}
43
44 empty = Empty
45
46 Empty <> y = y
47 x <> Empty = x
48 x <> y = x `Concat` y
49
50 char :: Char -> Doc
51 char c = Char c
52

```

screenshot

Loose ends

- ▶ Haskell can deal with infinite values, and so can QuickCheck. However, properties must not inspect infinitely many values. For instance, we cannot compare two infinite values for equality and still expect tests to terminate. Solution: Only inspect finite parts.
- ▶ QuickCheck can generate functional values automatically, but this requires defining an instance of another class `Coarbitrary` – but showing functional values is problematic.
- ▶ QuickCheck has facilities for testing properties that involve IO, but this is more difficult than testing pure properties.

Summary

QuickCheck is a great tool:

- ▶ A domain-specific language for writing properties.
- ▶ Test data is generated automatically and randomly.
- ▶ Another domain-specific language to write custom generators.
- ▶ Use it!

However, keep in mind that writing good tests still requires training, and that tests can have bugs, too.
